Introduction, Summary Conclusions and Recommendations

1.1 Introduction

On December 22, 2008 the dike of a coal combustion waste (CCW) ash pond dredging cell failed at a facility owned by the Tennessee Valley Authority in Kingston, Tennessee. The failure resulted in a spill of over one billion gallons of coal ash slurry, which covered more than 300 acres, damaging infrastructure and homes. In light of the dike failure, the United States Environmental Protection Agency (USEPA) is assessing the stability and functionality of existing CCW impoundments at coal-fired electric utilities to ensure that lives and property are protected from the consequences of a failure.

This assessment of the stability and functionality of the FirstEnergy Corp's Albright Power Station CCW impoundments is based on a review of available documents, site assessments conducted by CDM Smith on September 18, 2012, and technical information provided subsequent to the site visit. In summary, the North and South Process Wastewater Lagoon's embankments are classified as **POOR** for continued safe and reliable operation because static and seismic engineering studies following the best professional engineering practice to support acceptable safety factors have not been presented for the embankments.

It is critical to note that the condition of the embankment(s) depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the embankment(s) will continue to represent the condition of the embankment(s) at some point in the future. Only through continued care and inspection can there be likely detection of unsafe conditions.

1.2 Purpose and Scope

CDM Smith was contracted by the USEPA to perform site assessments of selected surface impoundments. As part of this contract, CDM Smith conducted site assessments of the North Process Wastewater Lagoon (North Lagoon) and South Process Wastewater Lagoon (South Lagoon) at the Albright Power Station site owned by FirstEnergy Corp. These ponds are located on the north and south sides of the site, respectively. The purpose of this report is to provide the results of the assessments and evaluations of the conditions and potential for waste release from the CCW impoundments.

A site visit was conducted by CDM Smith representatives on September 18, 2012, to collect relevant information, inventory the impoundments, and perform visual assessments of the impoundments.

1.3 Conclusions and Recommendations

1.3.1 Conclusions

Conclusions are based on visual observations during site assessment on September 18, 2012 and review of technical documentation provided by FirstEnergy Corp.

1.3.1.1 Conclusions Regarding Structural Soundness of the CCW Impoundments

Areas of erosion near the inlet pipes at the South Lagoon may cause localized structural stability issues in the future, but there was no instability of the embankment based on the observations by CDM Smith during the site assessment. Lateral movement of a retaining wall near the southwest corner of the North Lagoon does not appear to be adversely impacting the structural integrity of the North Lagoon. The walls were installed to provide excavating equipment access to the entire perimeter of the impoundment and do not appear to be required for operation of the impoundment.

Very limited and preliminary static slope stability analysis information was provided to assess the structural stability and soundness of the embankments of the North and South Lagoons.

1.3.1.2 Conclusions Regarding the Hydrologic/Hydraulic Safety of CCW Impoundments

Hydrologic and hydraulic information provided by the FirstEnergy Corp representative indicate CCW impoundments have adequate capacity to withstand a 25-year, 24-hour storm event without overtopping at normal pool level. It should be noted that the water level in the North Lagoon was approximately 3.5 feet above normal pool elevation during the site assessment. Normal pool elevation is based on the weir elevation at the outlet structure. The water level in the North Lagoon was elevated because the South Lagoon was being dredged at the time of the site visit.

However, the only documentation regarding the hydraulic capacity of the impoundments was in the form of an e-mail from the FirstEnergy Corp representative. No probable maximum precipitation (PMP) analysis was provided, as required under Federal Emergency Management Agency (FEMA) standards.

1.3.1.3 Conclusions Regarding Adequacy of Supporting Technical Documentation

Supporting data and documentation for the North and South Lagoons have not been provided. Slope stability analyses and liquefaction potential analyses for embankment foundations have not been performed.

1.3.1.4 Conclusions Regarding Description of the CCW Impoundments

The record drawings and descriptions of the CCW impoundments provided by FirstEnergy Corp representatives appear to be consistent with the visual observations by CDM Smith during the site assessment, with the exception of the retaining wall located at the North Lagoon's west embankment. The 2008 modifications to the North and South Lagoon weir structures and modifications to the outfall piping at the North Lagoon were not included on the provided record drawings.

1.3.1.5 Conclusions Regarding Field Observations

During visual observations and site assessments, CDM Smith observed lateral movement of the existing retaining wall at the interior slope of the North Lagoon's west embankment, and areas of erosion near the inlet pipes at the interior north and west embankment slopes of the South Lagoon. Dense vegetation was observed on the northeast embankment, exterior slope of the North Lagoon, adjacent to the Cheat River.

The growth of woody vegetation on and near dams, including the exterior toe area, can lead to serious problems. Sudden uprooting of trees by strong winds can result in the movement of a relatively large amount of embankment material and create large voids in the embankment. The uprooting in turn can lower the crest of the dam, reduce the effective width of the dam, lead to instability of the embankment, and facilitate seepage. The root systems of trees can be a potential hazard by allowing seepage pathways to develop through a dam. Trees eventually die and their roots decay and rot. The root cavity leaves a void within the dam through which water can enter and flow. The seepage paths can ultimately lead to failure of the dam by piping (internal erosion). In general, a tree's root system may extend to the edge of the tree canopy or tree drip line.

Brush and woody vegetation and tall grass prevent the proper visual inspection of the dam surfaces. The observation of sinkholes, slides, animal burrows, seeps, and other irregularities can be obscured by the vegetation. Woody vegetation can also cause excessive shade which in turn can hinder the growth of sturdy, dense grass coverage. These affected areas are more prone to surface erosion.

1.3.1.6 Conclusions Regarding Adequacy of Maintenance and Methods of Operation

Current maintenance and operation procedures appear to be inadequate. The inspections performed twice a month have no formal procedure and are not documented. At the time of CDM Smith's site assessment there was approximately 0.5 feet of freeboard in the North Lagoon because the South Lagoon was being dredged. The water surface was at approximately El. 1213.5.

A telephone memo prepared by GAI Consultants, Inc. (GAI), dated November 8, 1976. documenting a telephone call between Ralph Curtiss of GAI and M.P. Fedorov of Sanderson & Porter, Inc (S&P) states the calculated factor of safety of the North Lagoon embankments under cleaning equipment surcharge; with a rock berm at the toe of the interior embankment; and a maximum water level of El. 1211 (3 feet of freeboard) is 1.46.

There was no existing evidence of previous seepage, spills, or release of impounded liquids outside the plant property.

1.3.1.7 Conclusions Regarding Adequacy of Surveillance and Monitoring Program

The surveillance, recording, and monitoring program for the West Virginia Department of Environmental Protection (WVDEP) under the National Pollutant Discharge Elimination System (NPDES) Permit appears to be adequate and comply with WVDEP requirements.

1.3.1.8 Conclusions Regarding Suitability for Continued Safe and Reliable Operation

Main embankments do not show evidence of unsafe conditions requiring immediate remedial efforts, although maintenance to correct deficiencies noted above is required.

FirstEnergy Corp's Emergency Action Plans (EAPs) for the North and South Lagoons includes methods of controlling the water levels in the lagoons, but no formal documentation was provided to CDM Smith.

1.3.2 Recommendations

Based on CDM Smith's visual assessment of North and South Lagoons and review of documentation provided by FirstEnergy Corp, CDM Smith offers the following recommendations for consideration.

1.3.2.1 Recommendations Regarding the Hydrologic/Hydraulic Safety

It is recommended that a qualified professional engineer determine the required flood frequency and evaluate the hydrologic and hydraulic capacity of the lagoons to withstand design storm events without overtopping.

1.3.2.2 Recommendations Regarding the Technical Documentation for Structural Stability

It is recommended that a qualified professional engineer evaluate the static and seismic stability on representative embankment cross sections and perform liquefaction analyses for both the North and South Lagoons to enable a potential fair or satisfactory rating for structural stability.

1.3.2.3 Recommendations Regarding Field Observations

CDM Smith observed lateral movement of the retaining wall at the interior slope of the North Lagoon's south embankment. Lateral movement was not measured, but it appeared that the wall has moved several inches out of plumb. In CDM Smith's opinion, additional movement and/or collapse of the wall will not adversely impact the structural integrity of the North Lagoon, however First Energy Corp may find it advantageous to have a qualified professional engineer evaluate the stability of the wall and provide recommendations for remediation as appropriate. It is further suggested that FirstEnergy Corp may want to monitor wall movement prior to completion of the stability analyses.

Areas of erosion were observed on the interior slopes of the north and west embankments of the South Lagoon near inlet pipes. To restore areas of erosion, it is recommended to place riprap to adjacent existing grade contours or place and compact structural fill, grade to adjacent existing contours, and apply grass seed.

Trees and dense vegetation observed on the northeast embankment, exterior slope of the North Lagoon, adjacent to the Cheat River, should be removed and the embankment slope restored to the original contours by placing structural fill and compacting, as recommended by a qualified professional engineer. After slope restoration, it is recommended to stabilize the exposed surface of the embankment with sod, hydro seeding, or riprap consisting of a heterogeneous mixture of irregular-shaped rocks placed over the compacted fill and a geotextile fabric. Regular maintenance activities should be performed at least twice a year or as conditions warrant from the spring to fall to control and limit growth of vegetation on the embankments.

1.3.2.4 Recommendations Regarding Surveillance and Monitoring Program

Monitoring for potential seepage at the exterior embankment slopes is recommended for both the North and South Lagoons. Potential areas of seepage may be more readily assessed after clearing of trees and dense vegetation.

1.3.2.5 Recommendations Regarding Continued Safe and Reliable Operation

Inspections should be made following periods of heavy and/or prolonged rainfall and/or high water events on the Cheat River, and the occurrence of these events should be documented. Inspection procedures should be documented and inspection records should be retained at the facility for a minimum of three years.

Major repairs and slope restoration should be designed by a registered professional engineer experienced with earthen dam design.

None of the conditions observed require immediate attention or remediation, however, the above recommendations should be implemented to maintain continued safe and reliable operation of the CCW impoundments.

1.4 Participants and Acknowledgment

1.4.1 List of Participants

CDM Smith representatives, James Vinson, P.E. and Bevin Barringer, P.E, were accompanied at all times during the visual assessment by a representative from FirstEnergy Corp, William Cannon.

1.4.2 Acknowledgement and Signature

CDM Smith acknowledges that the CCW impoundments referenced herein were assessed by James Vinson, P.E. and Bevin Barringer, P.E. Based on the limited documentation provided and the inadequate stability analyses, the North and South Process Wastewater Lagoons are rated **POOR**. The facility lacks static and seismic engineering studies following best professional engineering practice to support safety factors under normal loading conditions (static, hydrologic, seismic) in accordance with the applicable safety regulatory criteria. Minor deficiencies exist that require remedial measures.

We certify that the CCW impoundments referenced herein have been assessed on September 18, 2012.

James Vinson, P.P. SONAL ET Geotechnical Engineering

West Virginia Registration No. 018380

Bevin Barringer, P.E. Geotechnical Engineer

Description of the Coal Combustion Waste (CCW) Impoundments

2.1 Location and General Description

The Albright Power Station (Station), owned by FirstEnergy Corp, is located in Preston County just off of County Route 7/12 in Albright, West Virginia, along the west bank of the Cheat River as shown on **Figure 2-1**. Critical infrastructure within approximately five miles downgradient of the Station is shown on **Figure 2-2**. The Cheat River serves as the northern and eastern property boundary of the Station. Open grassy areas with patches of trees are located to the west and south of the Station, as shown on **Figure 2-3**. The Cheat River runs south to north near the Station, and the City of Albright is on the opposite side of the Cheat River just downstream of the Station. The surrounding areas consist mostly of wooded mountains and hills.

The Station has two Coal Combustion Waste (CCW) impoundments: the North Process Wastewater Lagoon (North Lagoon) near the north end of Station property and the South Process Wastewater Lagoon (South Lagoon) near the south end of Station property as shown on Figure 2-3. The lagoons were created by excavation and the majority of the embankments are within three feet of original grade. The lagoons were constructed as combined incised/diked structures. The majority of the embankments are within three feet of original grade. Station stopped generating electricity in August 2012, and FirstEnergy Corp has plans to demolish the Station in the future.

The total perimeter of the North Lagoon is approximately 900 feet, and the surface area of the impoundment is approximately 0.85 acre. The total perimeter of the South Lagoon is approximately 1,030 feet, and the surface area of the impoundment is approximately 1 acre. **Table 2-1** shows a summary of the approximate size and dimensions of the impoundment embankments.

Table 2-1 – Summary of Impoundment Embankment Approximate Dimension and Size

	Impoundment	
	North Lagoon	South Lagoon
Maximum Embankment Height (feet)	13 ⁴	3
Width (feet)	20 to 25	20 to 25
Length¹ (feet)	900	1030
Interior Slopes, ² H:V	3:1 (west 2:1)	3:1
Exterior Slopes, ³ H:V	1:1 to 3:1	1:1 to 2:1

- 1. Length was measured along the perimeter crest of each impoundment/unit.
- 2. Interior slopes taken from construction drawings.
- 3. Exterior slopes estimated from topography shown on construction drawings.
- 4. Northwest corner of the North Lagoon, where natural grade slopes downward to the Cheat River, otherwise maximum embankment height is approximately 3 feet.

ALBRIGHT POWER STATION ALBRIGHT , WEST VIRGINIA CRITICAL INFRASTRUCTURE PLAN FIGURE 2-2

ALBRIGHT POWER STATION ALBRIGHT, WEST VIRGINIA SITE PLAN FIGURE 2-3

2.1.1 Horizontal and Vertical Datum

Project drawings dated 1977 and 2008, provided by FirstEnergy Corp. to CDM Smith, reference various horizontal and vertical datum's. Horizontal survey data on the original construction drawings from 1977 are referenced to baselines shown on earlier drawings that were not provided. Elevations shown on the 1977 drawings are referenced to the National Geodetic Vertical Datum of 1929 (NGVD 1929). The 2008 project drawings are referenced the North Zone of the West Virginia State Plane Coordinate System based on North American Datum of 1983 (NAD 83) and the North American Vertical Datum (NAVD 88). Elevations noted herein are in feet and are referenced to NAVD 88, unless otherwise noted.

2.1.2 Site Geology

The Albright Power Station is located along the western bank of the Cheat River in northern West Virginia. Based on review of the USGS Topographic Map, natural ground surface elevations in the area of the Station range from approximately El. 1200 to El. 1240. According to the Geologic Map of West Virginia published by the West Virginia Geological and Economic Survey, the Station is located on deposits from the Paleozoic Era. These deposits consist of cyclic sequences of sandstone, red beds, shale, limestone, and coal. According to the United States Geologic Survey, surface soils in the area mainly derive from red and gray shale, siltstone, and sandstone, with thin limestones and coals.

Soil borings provided by FirstEnergy Corp indicate that the North and South Lagoons' embankment fill consist of very loose to medium dense silty sand underlain by a layer of medium dense to very dense clayey silt, silty sand and gravel, with top of bedrock ranging from 25 to 30 feet below ground surface. Soil boring information provided and boring locations are included in **Appendix A**.

2.2 Coal Combustion Residue Handling

At the time of CDM Smith's on-site assessment, the power plant was closed and not producing CCW. CCW from the North Lagoon had recently been dredged and disposed of off-site, and dredging operations were underway at the South Lagoon. According to FirstEnergy Corp, the only liquids received by the North Lagoon, since the Station's closure, have been from stormwater runoff and other plant-generated liquids received after treatment at the onsite wastewater treatment facility. Due to the dredging operations, the South Lagoon was not receiving liquids and was nearly dry. Both lagoons have outlets that discharge into the Cheat River.

Because of the potential presence of residual CCW, and because the North and South Lagoons have not been formally closed in compliance with applicable federal or state closure/reclamation regulations, CDM Smith performed a condition assessment of the two impoundments as per USEPA requirements.

2.2.1 Bottom Ash

The Station's generating units are dry-bottom boilers with wet sluicing of bottom ash to a hydrobin. During Station operation, the source of the sluice water was re-circulating cooling tower blowdown. The water was then decanted from the hydrobin and transferred to either the North or South Lagoon. Once primary settling had occurred in the lagoon(s) the water was pumped to a clarifier-based treatment plant where chemical precipitation occurred prior to discharge to the Cheat River. The North and South Lagoons were generally dredged prior to reaching 60% of their storage capacities. Excavated bottom ash was sold for beneficial use or transferred to the Station's active landfill in

accordance with NPDES Permit No. WV0075281. Solids accumulated within the clarifiers were filter-pressed and transferred to the Station's landfill.

2.2.2 Fly Ash

During Station operation, fly ash produced at the Station is handled dry and transported to an on-site silo for temporary storage before being transported to the Station's landfill.

2.2.3 Boiler Slag

Albright Power Station does not produce boiler slag.

2.2.4 Flue Gas Desulfurization Gypsum

Albright Power Station does not have flue gas desulfurization equipment.

2.3 Size and Hazard Classification

According to the United States Army Corps of Engineers (USACE) Guidelines for Safety Inspection of Dams (1979) (ER 1110-2-106), impoundments are categorized per **Table 2-2**.

Table 2-2 - USACE ER 1110-2-106 Size Classification

Category	Impoundment		
Category	Storage (Ac-ft)	Height (Ft)	
Small	50 to < 1000	25 to < 40	
Intermediate	1000 to < 50,000	40 to < 100	
Large	> 50,000	> 100	

According to Dam Safety Rules (47CSR34) established by the West Virginia Department of Environmental Quality for coal-related dams, dams are defined as an artificial barrier or obstruction which is twenty-five (25) feet or more in height from the downstream stream bed and impounds fifteen (15) acre-feet or more of water, or is six (6) feet or more in height from the downstream stream bed and impounds fifty (50) acre-feet or more of water.

The total storage capacity of the North and South Lagoons are approximately 11 and 13 Acre-feet, respectively. Both impoundments have a maximum embankment height of approximately 3 feet. The lone exception is at the northwest corner of the North Lagoon, where the embankment exterior slope is natural grade that slopes downward to the Cheat River. At this location the embankment is approximately 13 feet in height. Therefore, neither lagoon is considered a dam as defined in ER 1110-2-106 and 47CSR34. The impoundment capacities were estimated by CDM Smith based on the impoundment geometry shown on the 1977 construction project drawings provided by FirstEnergy Corp.

It is not known if the Station impoundments currently have an assigned Hazard Potential Classification. Based on the USEPA classification system as presented on Page 2 of the USEPA checklist (**Appendix B**) and CDM Smith's review of the site and downstream areas, recommended hazard ratings have been assigned to the impoundments as summarized in **Table 2-3**:

Table 2-3 – Recommended Impoundment Hazard Classification Ratings

Ash Pond Unit	Recommended Hazard Rating	Basis
North Process Wastewater	Low Hazard	 Failure or miss-operation would result in low economic loss and environmental damage to adjacent waterways and downstream areas.
Lagoon		 Loss of human life as a result of failure is not anticipated.
South Process Wastewater	Low Hazard	 Failure or miss-operation would result in low economic loss and environmental damage to adjacent waterways and downstream areas.
Lagoon		 Loss of human life as a result of failure is not anticipated.

2.4 Amount and Type of Residuals Currently Contained in the Unit(s) and Maximum Capacity

Ash in the North Lagoon was dredged in August 2012, and the South Lagoon was being dredged on September 18, 2012 during CDM Smith's site assessment. FirstEnergy Corp's stated belief is the amount of CCW within the lagoons after dredging is de minimus. Based on information provided by FirstEnergy Corp, the lagoons had been used to store bottom ash residuals from dewatering hydrobin liquids. The pool area of the North Lagoon and South Lagoon is approximately 0.85 and 1 acre, respectively. Decant water from the North and South Lagoons exits through a monitored National Pollutant Discharge Elimination System (NPDES) discharge point into the Cheat River.

2.5 Principal Project Structures

Principal structures of the North Lagoon include the following:

- Three 8-inch-diameter carbon steel inlet pipes at the south embankment interior slope that discharge process wastewater from the Station,
- One 18-inch-diameter plastic pipe at the south embankment interior slope that discharges stormwater runoff,
- One 36-inch-diameter concrete pipe that receives flow from the discharge v-notch weir structure near the north embankment,
- Earthen perimeter embankments composed of silty sand fill,
- A concrete crib retaining wall, approximately 120 feet long, near the southwest corner of the impoundment along the hillside just west of the impoundment access road, and
- A concrete crib retaining wall, approximately 75 feet long, at the interior slope of the west embankment near the southwest corner of the impoundment.

Principal structures of the South Lagoon include the following:

- Three 8-inch-diameter carbon steel inlet pipes at the north embankment interior slope that discharge process wastewater from the Station,
- One 8-inch-diameter ductile iron pipe at the west embankment interior slope that discharges coal pile runoff,
- One 36-inch-diameter concrete pipe that receives flow from the discharge v-notch weir structure near the south embankment, and
- Earthen perimeter embankments composed of silty sand fill, clayey silt, silty sand, and gravel

2.6 Critical Infrastructure within Five Miles Downgradient

Based on available topographic maps, surface drainage in the vicinity of the Albright Power Station appears to be to the north and west towards the Cheat River which flows south to north in this area. Critical infrastructure, including schools, hospitals, waterways, roadways and bridges, and other major facilities, identified within five miles downgradient of the Station include the following:

- Albright Power Station's electric substation
- Bridge and underlying dam on the Albright Power Station entrance road over the Cheat River
- Bridge on Albright Road over the Cheat River
- Albright Baptist Church

Discharge from both impoundments will flow directly into the Cheat River. There is no critical infrastructure between the impoundments and the river.

Liquids discharged from a breach of the impoundment embankments would most likely be absorbed by the Cheat River and is not expected to result in loss of human life.

Summary of Relevant Reports, Permits and Incidents

3.1 Summary of Reports on the Safety of the CCW Impoundments

Safety reports for the CCW impoundments were not available for CDM Smith's review during the course of this assessment. This information was requested in an email prior to CDM Smith's on-site assessment and again during the visit. The FirstEnergy Corp representative indicated to his knowledge there have been no known structural or operational problems associated with the CCW impoundments.

3.2 Summary of Local, State, and Federal Environment Permits

Currently, the CCW impoundments are regulated by the West Virginia Department of Environmental Protection.

The Albright Power Station was issued a permit under the National Pollutant Discharge Elimination System (NPDES) authorizing discharge to the Cheat River in accordance with effluent limitations, monitoring requirements, and other conditions set forth in the permit. The Plant's permit was issued on July 11, 2011. The permit number is WV0004723.

3.3 Summary of Spill/Release Incidents

According to FirstEnergy Corp representatives, the only releases from the impoundments would have been during a flood that occurred in November 1985 when flood water was measured at El. 1228 at the Station. No further information was provided on the duration of the flooding or the condition of the impoundments during or after the event.

Summary of History of Construction and Operation

4.1 Summary of Construction History

4.1.1 Impoundment Construction and Historical Information

The Albright Power Station began operation in 1952. Prior to its recent shutdown, the CCW was generated by three coal-fired steam electric generating units (Units 1, 2, and 3) that have a total capacity of 292 megawatts of power.

Historical information on the North and South Lagoons available for review included construction drawings dated 1977 when the current impoundments were constructed, and 1995 and 2007 when piping modifications were designed. Construction drawings and other documentation provided by FirstEnergy Corp are included in **Appendix C**. The 1977 drawings show existing smaller impoundments were expanded to create the current North and South Lagoons. The 1977 construction drawings addressed regrading in the area of the previously constructed impoundments and construction of the current impoundments and inlet/outlet structures. Features that were observed during the site assessment, but not included on the construction drawings, included two concrete crib retaining walls located on the west (uphill) side of the side-hill lagoon and stormwater inlet pipe at the North Lagoon and the coal pile runoff inlet pipe at the South Lagoon. The walls were installed to provide excavating equipment access to the entire perimeter of the impoundment. They extend along the base of the hillside west of the lagoon access road and along the interior slope of the west embankment.

Soil boring locations and subsurface soil profiles, shown in Appendix A, were included on the 1977 drawings. A total of twelve soil borings, six borings at each impoundment site, were performed. Based on the 1977 construction drawings, the present configurations of the North and South Lagoons were achieved by regrading and excavating into silty sand fill, clayey silt and gravel material. Embankment construction required up to 3 feet of fill in limited areas.

The North Lagoon was constructed as a side-hill configuration using the natural terrain that slopes down to the Cheat River. Only the northern and eastern embankments of the impoundment have an exposed exterior slope. Drawings dated 1977 indicate the north and east embankments were constructed with silty sand fill. The south and west sides of the North Lagoon do not include an exterior slope; the western side of the lagoon was constructed by excavating into the existing hillside and the southern side is incised. As shown on the drawings the north, south, and east embankment interior slopes were constructed at 3H:1V, while the west embankment interior slope was at 2H:1V. The north and east embankment's exterior slopes were kept at the natural grade and range from 1H:1V to 3H:1V according to topography shown on the construction drawings. Based on information provided by FirstEnergy Corp and visual observations, the North Lagoon embankment crest is at El. 1214 and crest width varies from about 20 to 25 feet. Under normal conditions, the North Lagoon water surface elevation is approximately 14 feet higher than the water surface of the Cheat River and the bottom of the North Lagoon impoundment is approximately 4 feet above the water surface of the Cheat River. A failure of the North Lagoon's east embankment would likely result in the release of the impoundment contents to the Cheat River.

The South Lagoon was constructed by regrading and excavating into clayey silt, silty sand and gravel. Construction of the embankments included placement of up to 3 feet of fill. According to the 1977 drawings, the interior slopes were constructed at 3H:1V. The north side of the lagoon is incised and does not have an exterior slope. Coal pile runoff drainage ditches are located adjacent to the west embankment. The south, east and west embankment exterior slopes are approximately 2H:1V. The toe of the south and east exterior embankment ties into natural terrain that slopes down to the Cheat River. A coal pile runoff drainage ditch is located along the toe of the west embankment. Based on information provided by FirstEnergy Corp and visual observations, the South Lagoon embankment crest is at El. 1223 around the perimeter and crest width varies from about 20 to 25 feet.

4.1.2 Significant Changes/Modifications in Design since Original Construction

Changes/modifications to the design include construction of two concrete crib retaining walls at the North Lagoon. The retaining walls are located on the west (uphill) side of the lagoon. The wall at the base of the hillside is approximately 3 feet high and 120 feet long. The wall on the interior slope of the west embankment is approximately 75 feet long. The wall on the interior slope extended below the water level, therefore the wall height is unknown. The FirstEnergy Corp representative did not have information on the design or construction of these walls. CDM Smith was unable to observe other changes/modifications to the interior of the North Lagoon due to the water level in the impoundment during the site assessment.

Construction drawings dated 1995 show modifications to the South Lagoon piping at the Cheat River outfall structure. Modifications included regrading the river bank to 2H:1V in the vicinity of the outfall piping, increasing the thickness of riprap armoring along the riverbank from 1 foot to 4 feet, and installing a 36-inch-diameter galvanized corrugated metal pipe extension to the end of the existing 24-inch-diameter concrete pipe. Though not included in the information provided to CDM Smith, it appears that a similar modification was made at the North Lagoon. During our site assessment, the outfall at the North Lagoon appeared to be a corrugated metal pipe and not concrete as shown on the 1977 drawings.

Construction drawings dated 2007 show the installation of new piping in the east embankment of the North Lagoon. Based on information provided by FirstEnergy Corp, the pipe was installed in an opencut trench approximately 10 feet below the crest elevation.

Washington Group International (WGI) conducted hydraulic analyses in 2007 and recommended lowering the normal pool elevation in both the North and South Lagoons by one foot, to El. 1210 and 1219, respectively. The lower pool elevations were recommended to achieve adequate storage capacity for a 25-year, 24-hour storm event in both lagoons, assuming the other lagoon was out of service. WGI Drawing 21199-12-11-313, "Waste Water Treatment System, North Lagoon & South Lagoon Conn. Pipe Drainage Pipe Layout Plan & Profile" with proposed modifications to lower the pool elevations is included in Appendix C. According to the FirstEnergy Corp representative, modifications to the outlet weirs were made in 2008 based on recommendations provided by WGI. Modifications consisted of cutting oval holes into the metal weirs 1 foot below the v-notch to lower the normal pool elevations in both the North and South Lagoons.

4.1.3 Significant Repairs/Rehabilitation since Original Construction

Information regarding major repairs or rehabilitation to the embankments of the lagoons was not provided. Evidence of modifications to lagoon embankments included the concrete crib retaining walls near the southwest corner of the North Lagoon. No information on the date of the retaining

walls' construction was provided. No evidence of prior releases or failures was observed on the embankments during CDM Smith's visual assessment. There was no documentation provided that indicates otherwise.

4.2 Summary of Operational Procedures

4.2.1 Original Operating Procedures

The North and South Lagoons at the Albright Power Station have historically been used as settling ponds for liquids received from bottom ash dewatering hydrobins and other plant wastes. Waste water streams discharged into the North and South Lagoons and whose decant water is ultimately released into the Cheat River have included:

- Liquid from bottom ash dewatering hydrobins
- Boiler blowdown
- Filter backwash
- Ion exchange waste
- Floor drain waste
- Yard drain waste
- Coal pile runoff
- Stormwater

4.2.2 Significant Changes in Operational Procedures and Original Startup

Prior to the recent Station shut down, no significant changes in operational procedures had been made to the North and South Lagoons. There was no documentation provided that indicates anything different.

4.2.3 Current CCW Impoundment Configuration

Because the Station is currently shut down and not generating electricity, the North and South Lagoons only receive liquids from plant drain waste, coal pile runoff, and stormwater.

The North and South Lagoons are currently configured as previously described and as shown on Figure 2-3. The approximate crest elevations of the embankments and pond areas are shown in **Table 4-1** below.

Table 4-1 – Approximate Crest Elevations and Surface Areas

Ash Pond	ApproximateEmbankment Crest Elevation (Feet)	Approximate Impoundment Surface Area (Acres)
North Process Wastewater Lagoon	1214	0.85
South Process Wastewater Lagoon	1223	1.0

As previously discussed, ash from the North Lagoon was dredged in August 2012 and the South Lagoon was being dredged during CDM Smith's site assessment in September 2012. Over the service life of the impoundments, ash has been periodically dredged prior to reaching approximately 60% of the lagoon storage capacity.

Under normal operating conditions, liquids are discharged to the North Lagoon through three 8-inch-diameter steel pipes located at the south embankment interior slope. As designed and permitted, liquid from the impoundment is normally discharged to an on-site wastewater treatment system and then to the Cheat River. Liquids flow over a metal v-notch weir structure near the north embankment into a 36-inch-diameter concrete outlet pipe to a sump structure. Liquid is pumped from the sump structure to a clarifier-based treatment plant where chemical precipitation occurs prior to discharge to the Cheat River. Discharge directly to the Cheat River, via 36-inch-diameter concrete pipe, is limited to emergency bypasses for flows in excess of the 25-year storm event. The 36-inch-diameter concrete pipe has a 36-inch-diameter corrugated metal pipe extension at the outfall.

Under normal operating conditions, liquids are discharged to the South Lagoon through three 8-inch-diameter steel pipes located at the north embankment interior slope. Liquids flow over a metal v-notch weir structure near the south embankment into a 24-inch-diameter concrete outlet pipe to a sump structure. Liquid is pumped from the sump structure to an on-site clarifier-based treatment plant where chemical precipitation occurs prior to discharge to the Cheat River. Discharge directly to the Cheat River, via 36-inch-diameter concrete pipe is limited to emergency bypasses for flows in excess of the 25-year storm event. The 36-inch-diameter concrete pipe has a 36-inch-diameter corrugated metal pipe extension at the outfall.

4.2.4 Other Notable Events since Original Startup

Information provided to CDM Smith regarding other notable events that impacted operations and/or regular maintenance and inspection of the lagoons included the date and flood water elevation of the November 1985 flood, as discussed in Section 3.

Field Observations

5.1 Project Overview and Significant Findings (Visual Observations)

CDM Smith performed visual assessments of the impoundments at the FirstEnergy Corp Albright Power Station site. Impoundments assessed included the North Lagoon and South Lagoon. These impoundments are located on the north and south ends of the site, respectively. The perimeter embankments of the North Lagoon are approximately 900 feet in length and approximately 13 feet in height. The perimeter embankments of the South Lagoon are approximately 1,030 feet in length and approximately 3 feet in height. The assessments were completed following the general procedures and considerations contained in Federal Emergency Management Agency's (FEMA's) Federal Guidelines for Dam Safety (April 2004) to make observations concerning settlement, movement, erosion, seepage, leakage, cracking, and deterioration. A Coal Combustion Dam Inspection Checklist and Coal Combustion Waste (CCW) Impoundment Inspection Form, developed by USEPA, was completed for each of the aforementioned impoundments. Copies of these forms are included in Appendix B. Photograph locations are shown on **Figures 5-1** and **5-2**, and photographs are included in **Appendix D**. Photograph locations were logged using a handheld GPS device. The photograph coordinates are listed in Appendix D.

CDM Smith visited the plant on September 18, 2012, to conduct visual assessments of the impoundments. The weather was generally cloudy with intermittent light rain with daytime high temperatures up to 68 degrees Fahrenheit. The daily total precipitation prior to the site visit is shown in **Table 5-1**. The data were recorded approximately 6.5 miles south of the Station at the National Interagency Fire Center (NIFC) operated Remote Automated Weather Station (RAWS) in Kingwood, West Virginia.

Table 5-1 – Approximate Precipitation Prior to Site Visit

Date of Site Visit – September 18, 2012			
Day	Date	Precipitation (inches)	
Monday	September 17	0.10	
Sunday	September 16	0.01	
Saturday	September 15	0.01	
Friday	September 14	0.01	
Thursday	September 13	0.01	
Wednesday	September 12	0	
Tuesday	September 11	0	
Monday	September 10	0	
Total	(September 10 - 17, 2012)	0.14	
Total	Month Prior to Site Visit (August 17 – September 17, 2012)	3.24	

Note: Precipitation data from NIFC RAWS. Station Location: Kingwood, WV. Lat. 39.407; Lon. -79.701; EL. 1869 (ft-NGVD29).

5.2 North Process Wastewater Lagoon

At the time of the assessment, the North Lagoon contained liquids with approximately 0.5 feet of freeboard. It was indicated by a FirstEnergy Corp representative that the lagoon was dredged between August 13 and 24, 2012 to remove accumulated ash. Based on information provided by the FirstEnergy Corp representative, since dredging, the Station has been out of service and the lagoon has not received any CCW.

5.2.1 Crest

The crest of the North Lagoon's north and east embankments appeared to be in satisfactory condition (Photographs 1, 9, 18 and 24). The 20- to 25-ft-wide crest of the embankment consists of compacted granular soils and gravel and is exposed to minimal vehicle traffic. No depressions or evidence of settlement were observed on the crest. The western side of the North Lagoon was constructed by excavating into the existing hillside and the southern side is incised.

5.2.2 Interior Slopes

Due to the impoundment water level during the assessment, only the upper 0.5 to 1 ft of the interior slopes were visible (Photographs 2, 11, 17, and 25). Reportedly, the interior slopes are 3H:1V at all embankments except the west embankment which is at 2H:1V. A concrete crib retaining wall was located at the interior slope of the west embankment, near the southwest corner. The wall was approximately 75 feet long. A section of the wall, approximately 10 feet long, appeared to be displaced laterally towards the impoundment (Photographs 22 and 23). No depressions or evidence of settlement were observed on the crest behind the section of displaced wall. The west side of the North Lagoon is cut into an existing side slope, therefore further movement or failure of the wall would not impact the integrity of the impoundment. Due to the water level and lack of documentation, the wall height is unknown. Vegetation covered the portions of the interior slopes that were visible. Inlet pipes are located at the interior slope of the south embankment (Photograph 25).

5.2.3 Exterior Slopes

The lagoon includes exterior slopes on the north and east embankments that range from approximately 1H:1V to 3H:1V. The south and west sides of the North Lagoon do not include an exterior slope; the western side of the lagoon was constructed by excavating into the existing hillside and the southern side is incised. Due to the terrain and perimeter fencing around the North Lagoon, the north and east exterior slopes were only visible from the embankment crests. Based on limited observations from the crest, the exterior slopes appear to be in satisfactory condition. The exterior slopes of the North Lagoon embankments are protected with riprap armor. Some minor brush was growing between the riprap (Photographs 5, 8, 10, 15, and 27). The Cheat River is at the east embankment's exterior toe (Photograph 3, 4, and 27).

5.2.4 Outlet Structures

As designed and permitted; liquids from the impoundment are normally discharged through a pipeline to an on-site wastewater treatment system, and then to the Cheat River. The North Lagoon's outlet structure consists of a metal v-notched weir near the north embankment discharging to a 36-inch concrete pipe. The outlet structure also includes an opening with removable stoplogs used to control the weir's invert elevation (Photograph 13). The stoplogs were removed during the site assessment. The weir and pipe were submerged at the time of visual assessment. The 36-inch-diameter concrete pipe discharges into a sump structure (Photograph 6) that directs liquids to the on-

site wastewater treatment plant and then to the Cheat River. Discharge directly to the Cheat River, via 36-inch-diameter concrete pipe, is limited to emergency bypasses for flows in excess of the 25-year, 24-hour storm event. The 36-inch-diameter concrete pipe has a 36-inch-diameter corrugated metal pipe extension at the outfall (Photograph 7).

5.3 South Process Wastewater Lagoon

At the time of the site assessment, the majority of liquids in South Lagoon had been drained and accumulated ash material was being removed by dredging. The South Lagoon had more than approximately 11 feet of freeboard. The lagoon was not receiving liquids during the site assessment. Based on information provided by the FirstEnergy Corp representative, the Station has been out of service since August 2012 and the lagoon has not received any CCW since that time.

5.3.1 Crest

The north side of the South Lagoon is incised (Photograph 47). The south, east and west embankment crest appeared to be in satisfactory condition (Photographs 28, 32, 37 and 43). The crest width varied from 20 to 25 feet and consisted of compacted gravel and grass (Photographs 32, 37 and 43). The crest is exposed to minimal vehicle traffic. No depressions or evidence of settlement were observed.

5.3.2 Interior Slopes

Interior slopes appeared to be in fair condition (Photographs 29, 33, 36, and 45). Areas of erosion were located just downstream at each of the three inlets pipes at the north embankment (Photograph 31) and at the inlet pipe at the west embankment (Photograph 34). Based on construction drawings, the interior slopes are 3H:1V at all embankments. Grassy vegetation covered the upper portion of the interior slopes.

Three 8-inch-diameter inlet pipes are located at the interior slope of the north embankment (Photograph 30). One 18-inch-diameter inlet pipe is located at the interior slope of the west embankment (Photograph 34).

5.3.3 Exterior Slopes

The lagoon includes exterior slopes on the west, east, and south embankments. The north side of the South Lagoon is incised (Photograph 47). The west embankment exterior slope is a coal pile runoff drainage and storage ditch that was nearly full during the site assessment (Photographs 49, 51, and 52). The exterior slopes of the south and east embankments are approximately 2H:1V. The exterior slopes of the south and east embankments are generally covered with grass, between 3 and 4 inches in height and appear to be in satisfactory condition (Photographs 37 and 43). The Cheat River is located approximately 100 feet east of the South Lagoon (Photographs 56 and 62).

5.3.4 Outlet Structures

The outlet structure consists of a metal v-notched weir near the north embankment discharging to a 24-inch-diameter concrete pipe (Photographs 36, 39, 40 and 42). The outlet structure also includes an opening with removable stoplogs used to control the weir's invert elevation (Photograph 41). The stoplogs were removed during the site assessment. The 24-inch-diameter concrete pipe discharges into a sump structure (Photograph 58) that directs liquids to the on-site wastewater treatment plant, then to the Cheat River or an emergency bypass direct to the Cheat River may be implemented for flows in excess of the 25-year, 24-hour storm event (Photograph 60).

Hydrologic/Hydraulic Safety

6.1 Impoundment Hydraulic Analysis

The West Virginia Department of Environmental Protection (WVDEP) requirements related to the hydrologic or hydraulic design of CCW impoundments are included in Dam Safety Rule (47CSR34). According to 47CSR34, it appears that the North and South Lagoons are not subject to these requirements due to their size, as discussed in Section 2.3.

FEMA standards, as specified in "Federal Guidelines for Dam Safety" dated April 2004, require low hazard impoundments be designed for a flood frequency that takes into account loss of benefit risks, operation and maintenance costs, public confidence in dam safety, and local and state regulations. FEMA recommends that dams with a low-hazard potential should be designed for a flood having an average return frequency of no less than once in 100 years.

As mentioned in Section 4.1.2, based on information provided by FirstEnergy Corp, hydrologic and hydraulic analyses were conducted by WGI for the North and South Lagoons for 25-year, 24-hour storm events. Based on the analyses the normal pool elevation was lowered to El. 1210 at the North Lagoon and El. 1219 at the South Lagoon. This pool elevation provides storage for a 25-year, 24-hour storm event in both lagoons, assuming one of the two lagoons is out of service.

6.2 Adequacy of Supporting Technical Documentation

Results of the hydrologic and hydraulic analyses for the 25-year, 24-hour storm event were provided by a FirstEngergy Corp representative in a brief written summary, but it did not include any documentation. Using the normal pool elevations provided by FirstEnergy Corp, the freeboard at normal pool is 4 feet for the North and South Lagoons. Although at the time of CDM Smith's site assessment there was approximately 0.5 feet of freeboard in the North Lagoon because the South Lagoon was being dredged. No documentation or analyses for the PMP were provided.

6.3 Assessment of Hydrologic/Hydraulic Safety

Hydrologic and hydraulic safety of the Ash Pond appears to be **POOR** based on the following:

- A brief summary of WGI's hydrologic/hydraulic analyses was provided with no supporting documentation.
- During visual observations and site assessments, the freeboard in the North Lagoon was 3.5 feet above reported normal pool elevation.

An assessment of hydrologic/hydraulic safety of the Ash Pond is not possible at this time due to the lack of supporting documentation. According to FirstEnergy Corp representatives, releases from the impoundments likely occurred in November 1985 when Cheat River flood waters were measured at El. 1228 at the Station. No further information was provided on the duration of the flooding or the condition of the lagoons during or after the event.

Structural Stability

7.1 Supporting Technical Documentation

The available information regarding slope stability of the North and South Lagoons consists of a telephone memo prepared by GAI Consultants, Inc. (GAI), dated November 8, 1976. According to the memo, the telephone call was between Ralph Curtiss of GAI and M.P. Fedorov of Sanderson & Porter, Inc (S&P). S&P was the design engineer for the 1977 design, and GAI was the geotechnical consultant. No information is provided regarding the soil properties used in the analyses. The memo states that the factors of safety provided by GAI are based on calculations not fully checked. A copy of the memo is provided in Appendix C.

The memo states that the slope stability of the North Lagoon was analyzed with the crest elevation at El. 1214, bottom of impoundment elevation at El. 1201, maximum water level at El. 1211, and a 20-ft-wide crest, as shown on the 1977 drawings. The analyses were performed for interior slopes at 3H:1V subject to a cleaning equipment surcharge, with and without a rock berm at the toe; and for interior slopes at 2.5H:1V without a cleaning equipment surcharge. No further information was provided regarding the definition of "with and without cleaning equipment" conditions. Recommendations for the exterior slopes along the river bank including leaving existing slopes undisturbed, but any new slopes should be no steeper than 2.5H:1V. It was recommended riprap be added on the slope to the flood elevation. The memo also includes recommendations regarding the distance between the embankment crest and an undefined road.

The memo states that the slope stability of the South Lagoon was analyzed with the crest elevation at El. 1223, bottom of impoundment elevation at El. 1210, water level at El. 1220, and a 20-ft-wide crest, as shown on the 1977 drawings. The analyses were performed for interior slopes at 3H:1V with cleaning equipment, and at 2H:1V without cleaning equipment. The analyses assumed that the toe of the coal pile would be 30 feet from the top of the interior slope.

According to the telephone memo, slope stability factors of safety were developed under the assumption that partial drainage of slope occurs concurrently with lowering of the pool. And GAI stated that is not practical to design slopes in these soils to be stable with full pool drawdown at a rapid rate, no slope drainage, and no support from fly ash.

7.1.1 Stability Analyses and Load Cases Analyzed

The WVDEP requirements related to embankment stability of CCW impoundments are included in Dam Safety Rule (47CSR34), though as mentioned earlier, the North and South Lagoons are not classified as dams based on 47CSR34. The minimum factors of safety established by WVDEP are included in **Table 7-1**. Procedures established by the United States Army Corps of Engineers (USACE), the United States Bureau of Reclamation, the Federal Energy Regulatory Commission, and the Natural Resources Conservation Service are generally accepted engineering practice. Minimum required factors of safety outlined by the USACE in EM 1110-2-1902, Table 3-1 and seismic factors of safety by FEMA Federal Guidelines for Dam Safety, Earthquake Analyses and Design of Dams (pgs. 31, 32 and 38, May 2005) are also provided in Table 7-1.

Table 7-1 - Recommended Minimum Safety Factors

Load Case	Minimum Required Factor of Safety		
	WVDEP ¹	USACE ²	
Steady-State Condition at Normal Pool or Maximum Storage Pool Elevation	1.5	1.5	
Rapid Drawdown Condition from Normal Pool Elevation	1.2	1.3	
Maximum Surcharge Pool (Flood) Condition		1.4	
Seismic Condition from at Normal Pool Elevation	1.2	1.1	
Liquefaction		1.3	

Note: 1 - Based on required factors of safety published by WVDEP in 47CSR34.

7.1.2 Design Parameters and Dam Materials

No information was provided regarding the design parameters or material properties used in the slope stability analyses discussed in the 1976 telephone memo.

7.1.3 Uplift and/or Phreatic Surface Assumptions

The only information provided on the seepage conditions used in the geotechnical analyses were that slope stability factors of safety were developed under the assumption that partial drainage of slope occurs concurrently with lowering of the pool. No further information on assumptions was provided.

7.1.4 Factors of Safety and Base Stresses

A summary of safety factors computed for the different cases of the North and South Lagoons is included in **Table 7-2**.

Table 7-2 - Safety Factors Computed for Various Stability Conditions

Slope Geometry and Load Case	Factor of Safety
North Lagoon Interior Slope 3:1 – with cleaning equipment	1.25
North Lagoon Interior Slope 3:1 – with cleaning equipment and rock berm at toe	1.46
North Lagoon Interior Slope 2.5H:1V – without cleaning equipment	1.46
South Lagoon Interior Slope 3:1 – with cleaning equipment	1.45
South Lagoon Interior Slope 2H:1V – without cleaning equipment	1.42

Source: Telephone Memo, prepared by Ralph Curtiss, GAI, November 8, 1976.

Based on information provided in GAI's telephone memo of November 8, 1976, the calculated factors of safety were not fully checked and each of the load cases required by the USACE was not analyzed.

7.1.5 Liquefaction Potential

Documentation provided in the 1976 telephone memo did not include evaluation of liquefaction potential.

^{2 -} Based on required factors of safety published by USACE in EM 1110-2-1902.

7.1.6 Critical Geological Conditions

According to the Geologic Map of West Virginia published by the West Virginia Geological and Economic Survey, geology in the area of the Station consists of sandstone, red beds, shale, limestone, and coal. According to the United States Geologic Survey, surface soils in the area mainly derive from red and gray shale, siltstone, and sandstone, with thin limestones and coals.

Based on geographic location and the 2008 USGS National Seismic Hazard Map, Peak Ground Acceleration (PGA) for 2% probability of exceedance in 50 years is approximately 0.15g.

7.2 Adequacy of Supporting Technical Documentation

Structural stability documentation that has been provided was preliminary according to the documentation and is incomplete. Seismic and liquefaction potential analyses were not performed.

7.3 Assessment of Structural Stability

Because of the lack of documentation and analyses for required loading conditions and cross sections, and conditions observed during the September 18, 2012 site inspection, the assessed rating for the structural stability of the North and South Lagoons is **POOR**. As such, a dam safety rating of "POOR" is assigned when a dam safety deficiency is recognized for loading conditions that may realistically occur. Remedial action is recommended. POOR may also be used when uncertainties exist as to critical analysis parameters that identify a potential dam safety deficiency. Further investigations and studies are necessary.

Identified deficiencies include the following:

- Stability analyses of the North and South Lagoon embankments are incomplete and not well documented.
- Stability analyses for different surcharge loading, seepage, and seismic conditions, as well as liquefaction analyses are required to assess a satisfactory rating for structural stability. These types of analyses were not provided.
- During visual observations and site assessments of the North Lagoon, the high water level in the impoundment prevented observation of the interior slopes.
- Areas of erosion at the inlet pipes were observed at the South Lagoon's north and west interior slopes.
- Due to vegetation and riprap located on the northeast embankment, exterior slope of the North Lagoon, assessment of potential stability and seepage issues could not be made.

Adequacy of Maintenance and Methods of Operation

8.1 Operating Procedures

As described in Section 2, when the plant was in operation, both the North and South Lagoons received liquids from bottom ash dewatering hydrobins. At the time of CDM Smith's on-site assessment, the power plant was closed and not producing CCW. Ash material from the North Lagoon had recently been dredged and disposed of off-site, and dredging operations were underway at the South Lagoon. Since the Station's closure, the only liquids received by the North Lagoon have been from stormwater runoff and other plant-generated liquids received after treatment at the onsite wastewater treatment facility. Due to the dredging operations, the South Lagoon was not receiving liquids and was nearly dry. Both lagoons have sump structures that can direct liquids to the on-site wastewater treatment plant or to outfalls at the Cheat River.

8.2 Maintenance of the Dam and Project Facilities

The FirstEnergy Corp representative indicated during the site assessment by CDM Smith on September 18, 2012, visual inspections are performed for both the North and South Lagoons twice a month. The results of these inspections are not generally documented and no documentation of inspections was provided to CDM Smith.

The only regular maintenance operations include mowing North and South Lagoons' embankments.

8.3 Assessment of Maintenance and Methods of Operations 8.3.1 Adequacy of Operating Procedures

Based on CDM Smith's visual observations and the lack of documentation, existing Operating Procedures are considered to be **INADEQUATE**. Written documentation of Operating Procedures was not provided. At the time of CDM Smith's site assessment the water surface level in the North Lagoon was approximately 3.5 feet above the normal pool elevation because the South Lagoon was being dredged. The water surface was at approximately El. 1213.5, as such there was only 0.5 feet of freeboard in the North Lagoon.

8.3.2 Adequacy of Maintenance

Maintenance issues included high vegetation and trees on the on the northeast embankment, exterior slope of the North Lagoon, areas of erosion near the inlet pipes at the South Lagoon, water levels well above normal pool elevation in the North Lagoon, and lateral displacement of the North Lagoon retaining wall.

Based on the lack of documentation provided and observed deficiencies, the maintenance procedures are rated as **INADEQUATE**. A maintenance schedule and maintenance procedures should be developed to address these issues.

Adequacy of Surveillance and Monitoring Program

9.1 Surveillance Procedures

FirstEnergy Corp is required by WVDEP under their NPDES Permit No. WV0004723 to monitor discharge of wastewater into the Cheat River. Surveillance procedures should be in accordance with WVDEP – NPDES Permit.

FirstEnergy Corp indicated that they inspect the embankments for structural stability twice a month, but no documentation is maintained.

9.2 Instrumentation Monitoring

Based on the information provided by the FirstEnergy Corp representative the North and South Lagoon water levels are monitored remotely with instrumentation in the sump structure. The water levels recorded by the sump are in inches measured from the floor slab elevation of the sump structure. Water levels measured between May 29, 2012 and June 30, 2012 in both the North and South Lagoons are provided in Appendix C.

The North and South Lagoon embankments do not have an instrumentation monitoring system to monitor structural stability, seepage or ground displacement.

9.3 Assessment of Surveillance and Monitoring Program 9.3.1 Adequacy of Inspection Programs

Based on the documents reviewed by CDM Smith and visual observations during the site assessment, the inspection program appears to be adequate, but should be documented in the future. No conditions that needed immediate remedial actions were observed.

9.3.2 Adequacy of Instrumentation Monitoring Program

As mentioned before, instrumentation is not present within the embankments. Detrimental conditions or indications for potential failure of embankments were not observed at the North or South Lagoon. FirstEnergy Corp may find it advantageous to monitor lateral displacement of the retaining wall on the west interior slope of the North Lagoon; however in CDM Smith's opinion, additional movement and/or collapse of the wall will not adversely impact the structural integrity of the North Lagoon.

The water level instrumentation appears to be adequate as data are recorded nearly continuously and documented by the Station.

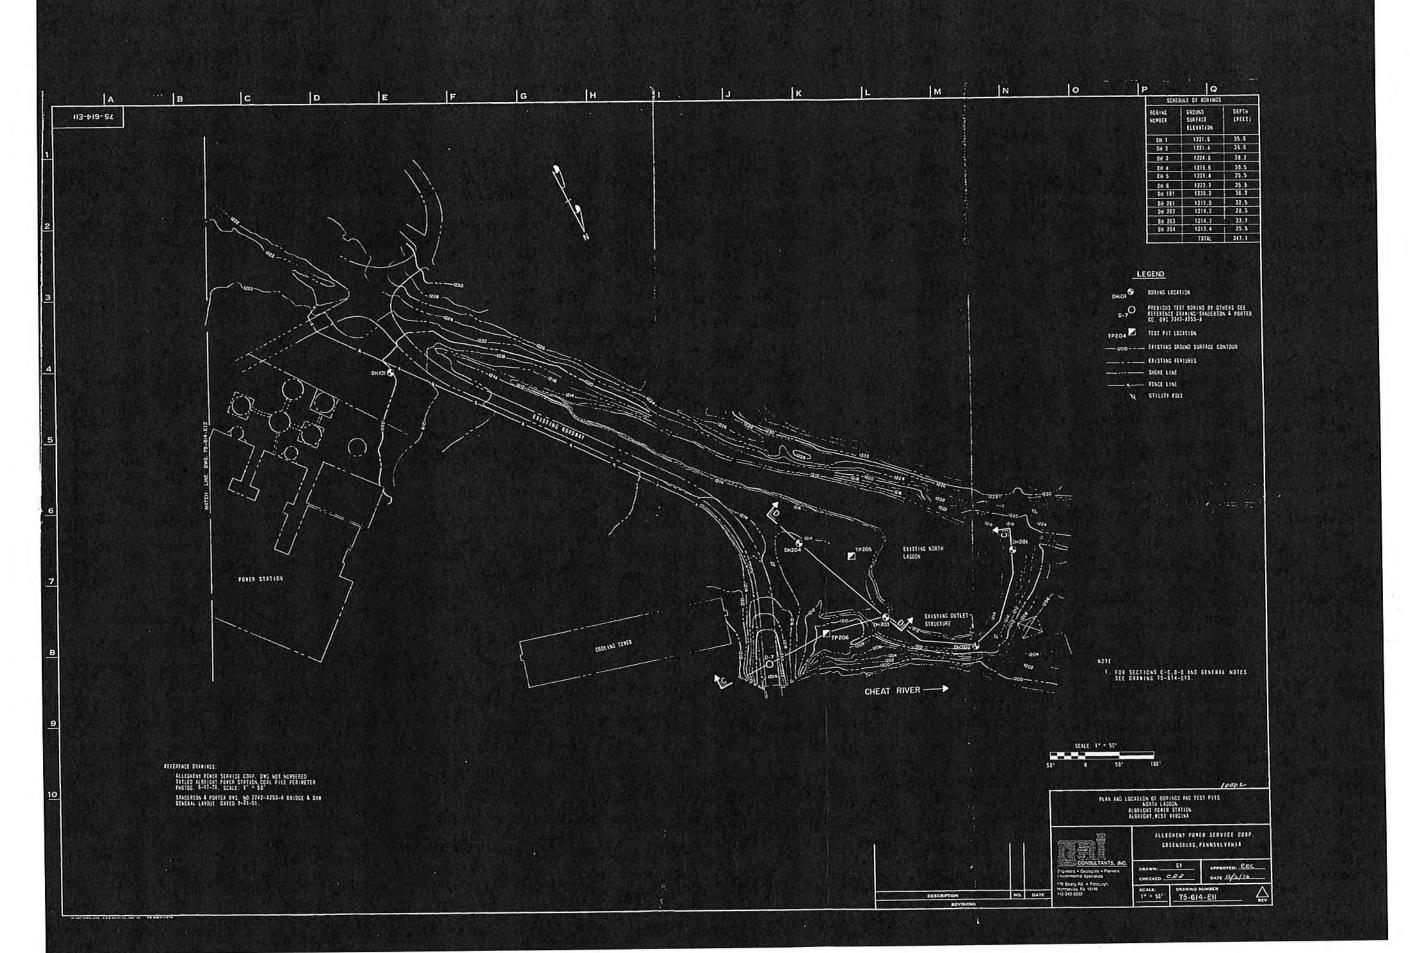

Reports and References

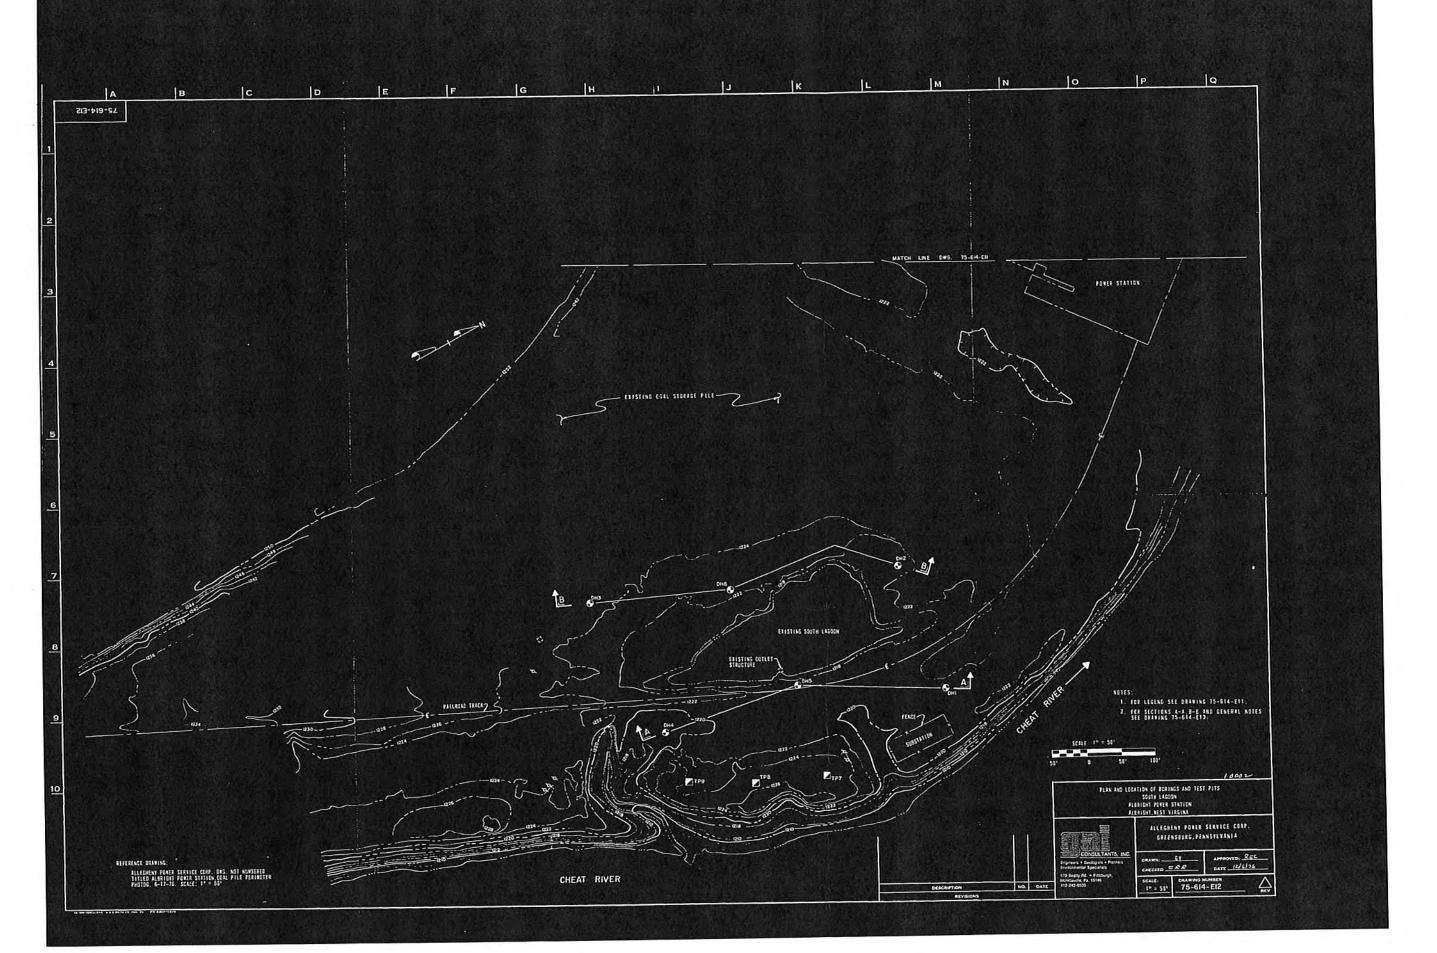

The following is a list of reports and drawings that were provided by FirstEnergy Corp and were used during the preparation of this report and the development of the conclusions and recommendations presented herein.

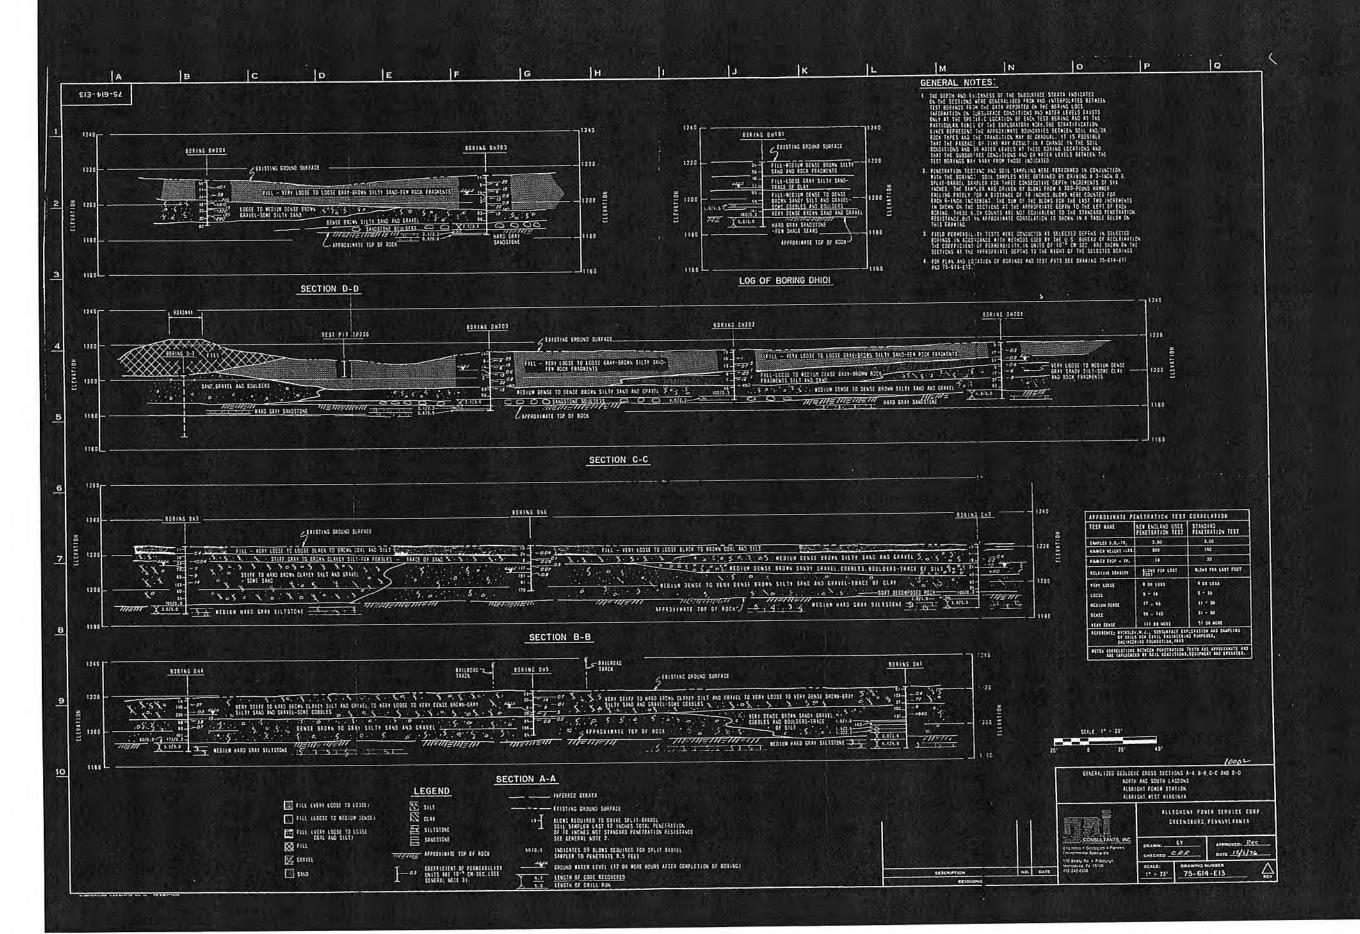

- 1. EPA Effluent Guidelines Questionnaire, prepared by Monongahela Power (now FirstEnergy Corp) to EPA, October 15, 2010.

17. Cracks or scarps on slopes?		Х	24. Were Photos taken during the dam inspection?	X	

Major adverse changes in these items could cause instability and should be reported for further evaluation. Adverse conditions noted in these items should normally be described (extent, location, volume, etc.) in the space below and on the back of this sheet.

Inspection Issue # Comments

- 1. Twice a month plant perimeter inspections and water sampling are performed. Staff will note if there are any issues, but no formal documentation exists.
- 3,12 Water drains over v-notched weir at El.1211 to outlet pipe at El.1203.6.
- 8. Construction documents indicate 6" of stripping prior to fill placement.
- 9. Largest tree is approximately 4 inches in diameter.
- 18. 10-ft-long section of 75-ft-long concrete crib retaining wall at west

interior slope was bulging towards the lagoon.

23. Cheat River at east embankment exterior toe.

HAZARD POTENTIAL (In the event the impoundment should fail, the following would occur):
LESS THAN LOW HAZARD POTENTIAL: Failure or misoperation of the dam results in no probable loss of human life or economic or environmental losses.
LOW HAZARD POTENTIAL: Dams assigned the low hazard potential classification are those where failure or misoperation results in no probable loss of human life and low economic and/or environmental losses. Losses are principally limited to the owner's property.
SIGNIFICANT HAZARD POTENTIAL: Dams assigned the significant hazard potential classification are those dams where failure or misoperation results in no probable loss of human life but can cause economic loss, environmental damage, disruption of lifeline facilities, or can impact other concerns. Significant hazard potential classification dams are often located in predominantly rural or agricultural areas but could be located in areas with population and significant infrastructure.
HIGH HAZARD POTENTIAL: Dams assigned the high hazard potential classification are those where failure or misoperation will probably cause loss of human life.
DESCRIBE REASONING FOR HAZARD RATING CHOSEN:
Due to the size of the impoundment and topography in the area, failure or
misoperation of the impoundment would likely result in minimal economic and environmental damage to the Cheat River located just north of the impoundment.

ADDITIONAL INSPECTION QUESTIONS

Concerning the embankment foundation, was the embankment construction built over wet ash, slag, or other unsuitable materials? If there is no information just note that.

Based on review of available documents, it appears the embankment foundation was not constructed over wet ash, slag or other unsuitable materials. Soil boring location plans, subsurface soil profiles and construction drawings dated 1977, indicate the present configuration of the North Lagoon was achieved by regrading and excavating into silty sand fill, clayey silt and gravel.

Did the dam assessor meet with, or have documentation from, the design Engineer-of-Record concerning the foundation preparation?

The assessor did not meet with, or have documentation from the design Engineer of Record concerning foundation preparation.

From the site visit or from photographic documentation, was there evidence of prior releases, failures, or patchwork on the dikes?

There was no indication of prior releases, failures or patchwork on the embankments.

ADDITIONAL INSPECTION QUESTIONS

Concerning the embankment foundation, was the embankment construction built over wet ash, slag, or other unsuitable materials? If there is no information just note that.

Based on review of available documents, it appears the embankment foundation was constructed over wet ash, slag or other unsuitable materials. Soil boring location plans, subsurface soil profiles and construction drawings dated 1977, indicate the present configuration of the South Lagoon was achieved by regrading and excavating into silty sand fill, clayey silt and gravel.

Did the dam assessor meet with, or have documentation from, the design Engineer-of-Record concerning the foundation preparation?

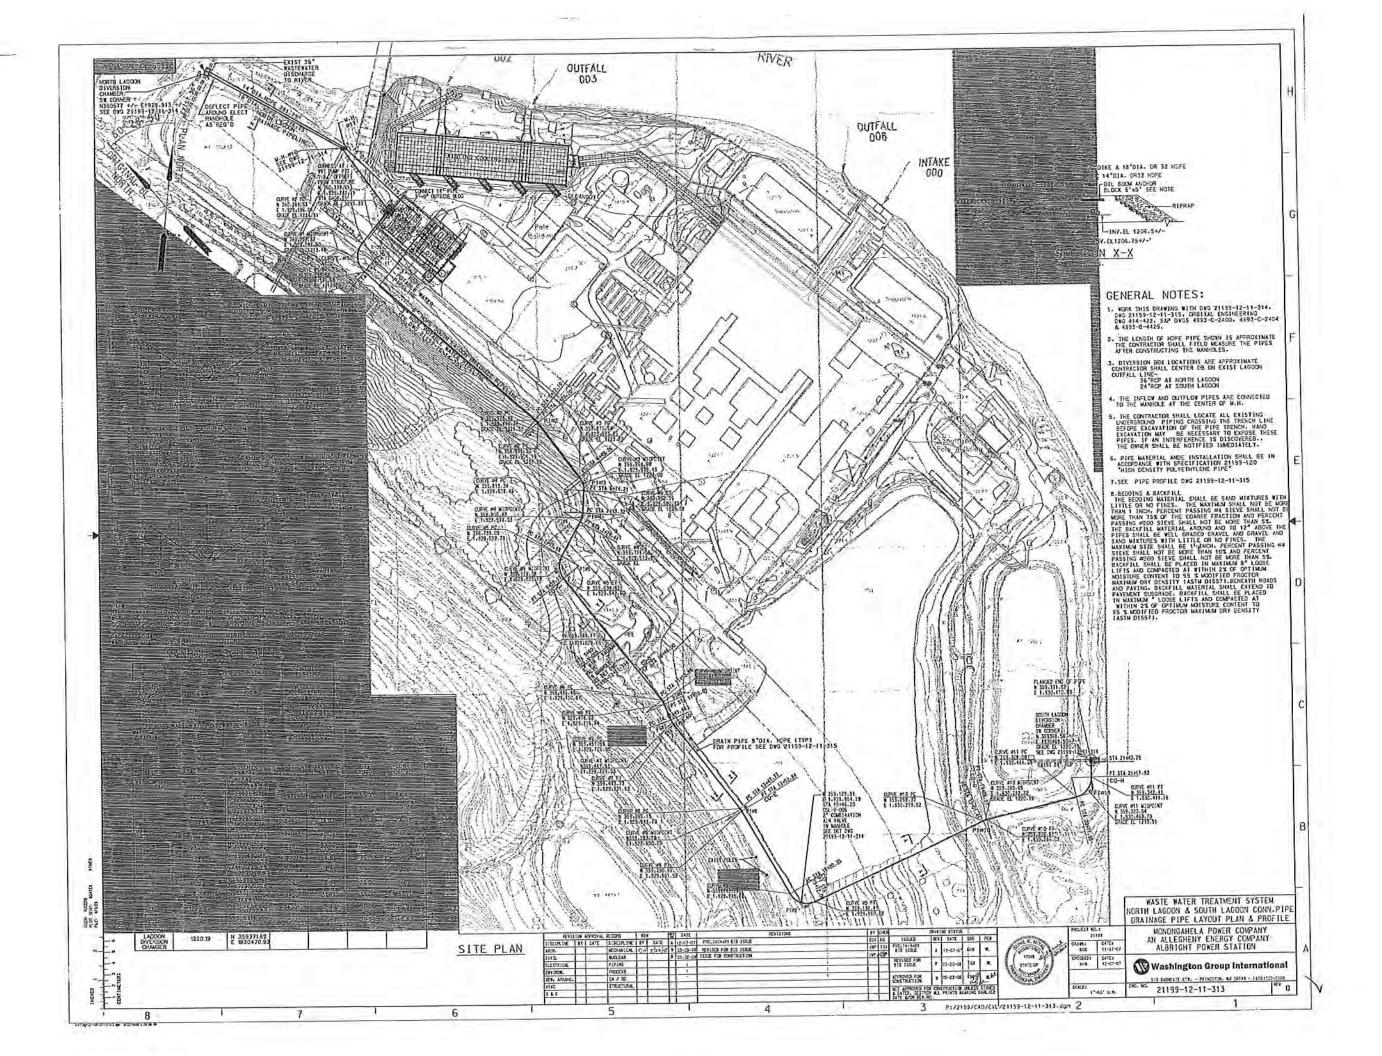

The assessor did not meet with, or have documentation from the design Engineer of Record concerning foundation preparation.

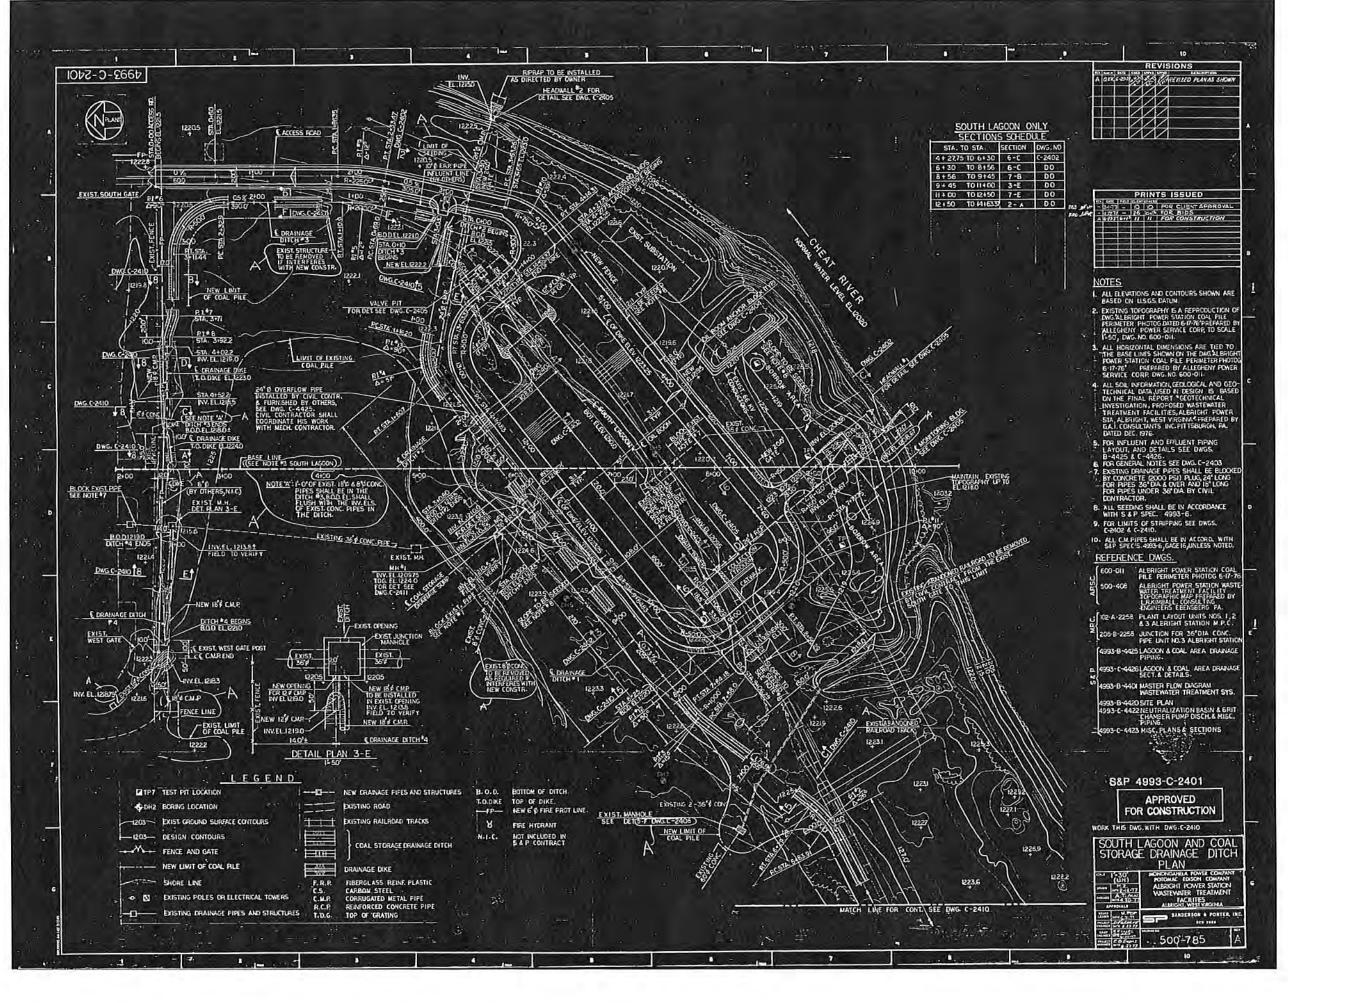

From the site visit or from photographic documentation, was there evidence of prior releases, failures, or patchwork on the dikes?

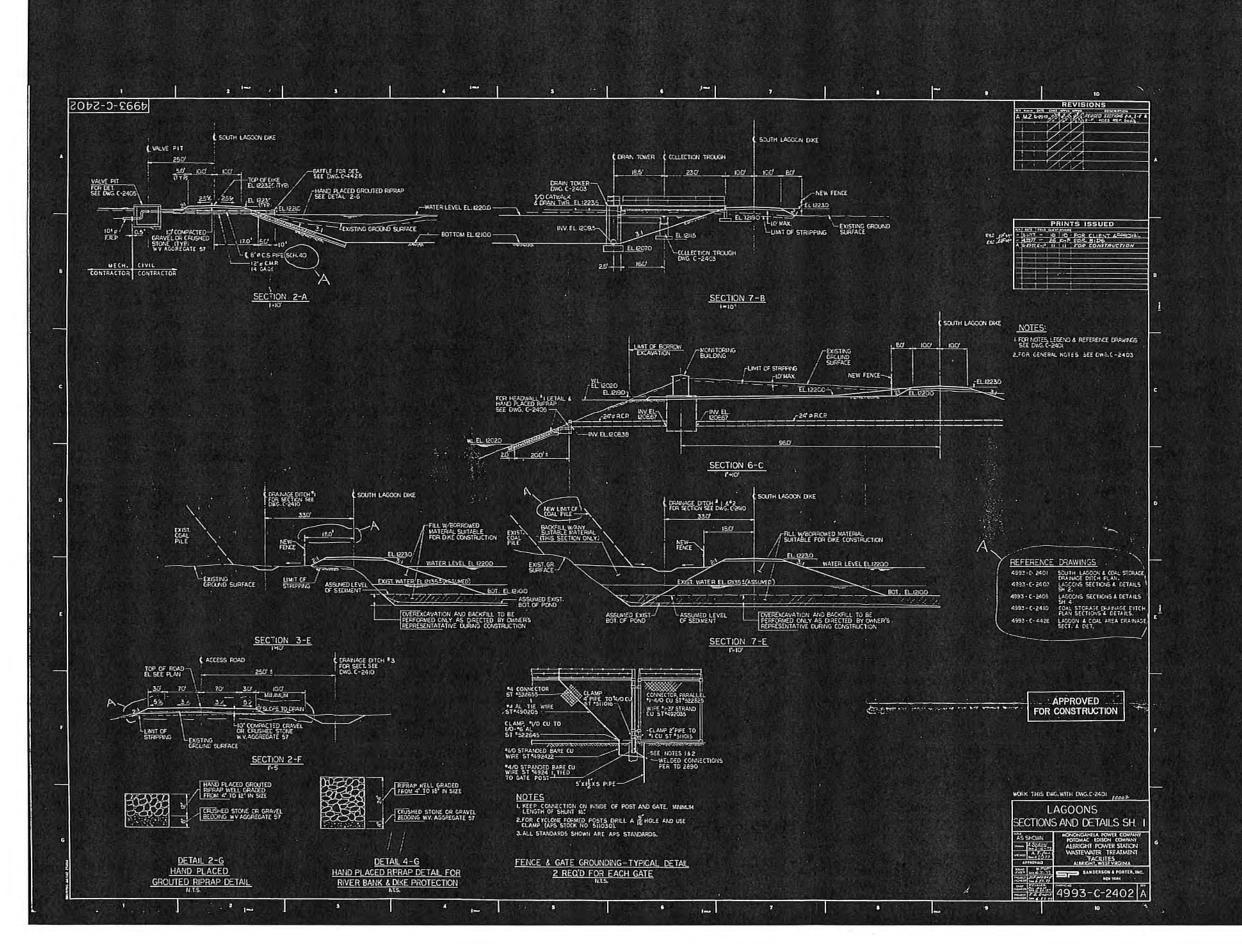

There was no indication of prior releases, failures or patchwork on the embankments.

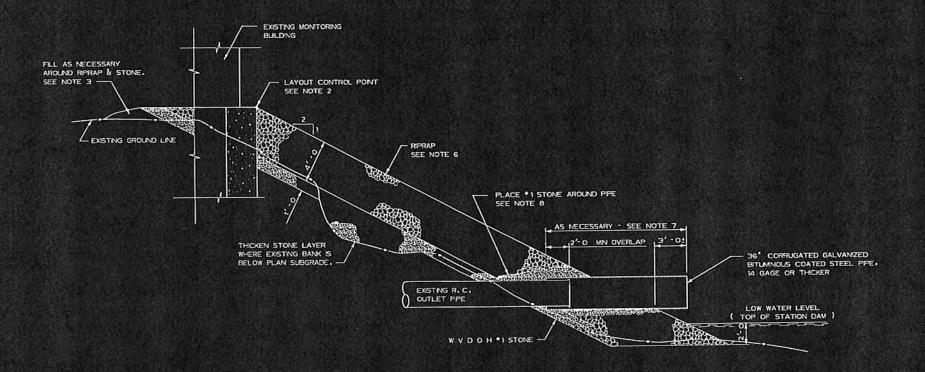

Appendix C

Documentation from FirstEnergy Corp

TYPICAL SECTION

NOTES 1

- 1. THE CONTRACTOR SHALL REPAIR THE RIVER BANK AS SHOWN IN THE TYPICAL SECTION FOR A DISTANCE OF 30 LINEAL FEET USTREAM AND DOWNSTREAM FROM THE SOUTH LAGGON OUTLET PIPE (60 LINEAL FEET TOTAL LENGTH).
- 2. AT THE MONITORING BUILDING, THE TOP OF THE PROPOSED RIPRAP SLOPE SHALL COINCIDE WITH THE LAYOUT CONTROL POINT (SEE TYPICAL SECTION). LPSTREAM AND DOWNSTREAM, THE PLAN LAYOUT SHALL FOLLOW THE EXISTING DAME OF THE RIVER BANK SLOH THAT THE RIPRAP SLOPE CONFORMS AS WELL AS POSSIBLE TO THE EXISTING BANK SLOPE AT THE ENDS. EXISTING RIVER BOLLOFES SHALL BE PLACED AT THE UPSTREAM AND DOWNSTREAM EDGS OF THE RIPRAP AS NECESSARY TO MAKE SMOOTH TRANSITIONS.
- 3. THE CONTRACTOR SHALL USE EXCAVATED

 MATERIAL AS NECESSARY TO FILL AND GRADE

 AROUND THE TOP OF THE RIPRIP AND STOVE TO

 ACHIEVE SHOOTH TRANSITIONS WITH EXIST ING

 GROUND. ALL FILL SHALL BE PLACED IN

 LAYER SON THICKER THAN ONE FOOT AND EACH

 LAYER COMPACTED BY AT LEAST SIX PASSES OF

 TRACKED EQUIPMENT. NO LOW SPOTS SHALL BE

 LEFT TO POND WATER.
- 4. THE CONTRACTOR SHALL DISPOSE OF EXCESS OR USUITABLE EXCAVATED MATERIAL IN THE ASH DISPOSAL AREA AT A LOCATION DESIGNATED BY THE OWNERS.
- 5. GRUSHED STOKE SHALL MEET THE QUALITY REQUIREMENTS OF WOOM 1982 SHECIFICATIONS SECTION 703, 1 AND THE GRADING REQUIREMENTS OF TABLE 703,4 FOR THE SIZE INDICATED.
- 6. RIPRAP SHALL BE GRADED FROM 6 TO 48
 IND-ES IN SIZE WITH AT LEAST 50 PERCENT
 BY WEIGHT HAVING NO DIMENSION SHALLER
 THAN 24 INC-ES, QUALITY SHALL MEET THE
 REQUIREMENTS OF WIDOH 1982 SPECIFICATIONS
 SECTION 704.2.
- 7. THE CONTRACTOR SHALL DETERMINE THE REQUIRED LENGTH OF CORRUGATED METAL PIPE SUCH THAT THE OVERLAP AND PROJECTION SHOWN ON THE TYPICAL SECTION ARE ACHIEVED.
- B. THE CONTRACTOR SHALL PLACE 1 STONE
 AROUND THE CONCRETE AND STEEL PIPES AS
 NECESSARY TO PREVENT DAMAGE FROM RIPRAP
 PLACEMENT.

Subject Geometry of South Lagoon at Albright Power Station LAGOON	
iummary of Discussion, Decisions and Commitments	
For the purposes of slope stability analysis, R. Curtiss	
and M. Fedorov worked out the following geometric details	
for the South Lagoon:	
1. Lagoon bottom elevation of 1210.0;	
2. Water level elevation of 1220.0;	
3. Dike top elevation of 1223.0;	
4. Dike top width of 20.0 ft.	
R. Curtiss and M. Boronky had decided earlier that the	 .
toe of the coal pile would be assumed to be 30 feet back of	
the top of the inside dike slope. Slope will be analyzed	
with cleaning equipment surcharges present.	17

For t	he purposes of slope stabi	ility analysis, R. Curtiss
and M. Fed	orov worked out the follow	wing geometric details for
the North	Lagoon in the vicinity of	the road:
1.	Lagoon bottom elevation of	f 1201.0. Outlet riser
	inside bottom elevation is	s 1197.9.
2	Maximum water surface elev	vation of 1211.0. Lowest
1	point on road is at elevat	tion 1214.
3.	where road is at or near e	elevation 1214, allow
	following space between ro	oad and top of lagoon
,	slope:	
	4 feet shoulder, 10 f	feet for storm sewer installation
	20 feet for top of di	ike.
4.	Where road is above elevat	tion 1214, allow following
	space between road and top	
	4 feet shoulder, slop	
	. elevation 1214.0, 20

Appendix E CDM Smith Memorandum of Explanation Draft Report Comments

11 British American Boulevard, Suite 200

Latham, New York 12110 tel: 518-782-4500 fax: 518-783-3810

Memorandum

To: Jana Englander

From: William J. Friers

Date: April 18, 2014

Subject: Round 12, Revised Final Report – Albright Power Plant

Please find attached a copy of the CCW Impoundment Final Report for Albright Power Station (Round 12, CLIN 012). This Final Report has been revised to address the comments received from the EPA and the Plant Owner, FirstEnergy comments have been addressed in the Final Report, as noted below.

<u>FirstEnergy's Comment No. 1</u> – FirstEnergy references Sections 1.3, 6.3 and 8.3 of the Draft Report that states: At the time of CDM Smith's site assessment, the North Lagoon was 3.5 feet above normal pool elevation. FirstEnergy notes the North Lagoon was above its normal pool elevation for the sole reason that the South Lagoon was being actively dredged during the assessment.

CDM Smith Action - CDM Smith has revised the report, indicating the reason for the North Lagoon's elevated water surface elevation.

<u>FirstEnergy's Comment No. 2</u> – FirstEnergy disputes the need to perform PMP analyses, because the North and South Lagoons' embankments are dams, as defined by ER 1110-2- 106.

CDM Smith Action - CDM Smith has not revised the recommendation that a qualified professional engineer determines the required flood frequency and evaluates the hydrologic and hydraulic capacity of the lagoons to withstand design storm events without overtopping. Overtopping of either lagoon may result in discharge to the Cheat River.

<u>FirstEnergy's Comment No. 3</u> – FirstEnergy disputes CDM Smith's recommendation to clear trees and dense vegetation adjacent to the Cheat River. FirstEnergy's contends the referenced trees and dense vegetation are natural species, the presence of which should be considered far more advantageous than detrimental in that it provides stabilization and protection for the river bank, and that the slopes referenced in CDM Smith's Draft Report are the natural bank of the Cheat River. FirstEnergy further contends the South Lagoon is incised.

CDM Smith Action - CDM Smith has revised the recommendation to include removal of trees and dense vegetation from only the northeast embankment, exterior slope of the North Lagoon. CDM Smith has also

CCW Impoundment Condition Assessment Report Albright Power Station (Round 12, CLIN 012) Page 2

included discussion in Section 1.3.1.5 of the Final Report regarding problems that may occur when trees and dense vegetation are allowed to grow on earth embankments.

CDM Smith does not agree with FirstEnergy's assertion that the South Lagoon is incised. While portions of the South Lagoon are incised, embankments have been constructed on the south and east sides of the Lagoon to maintain the crest elevation of approximately 1223'. By definition, an impoundment is "incised" only if the unit is fully incised. As such, the South Lagoon is considered a "side-hill" impoundment.

<u>FirstEnergy's Comment No. 4</u> – FirstEnergy proposes that the volume of CCW currently stored in the North and South Lagoons should be, for all reasonable purposes, considered de minimus based on recent dredging of the North Lagoon and the active dredging of the South Lagoon during CDM Smith's site assessment.

CDM Smith Action - CDM Smith has acknowledged in Section 2.2 of the Final Report that CCW had recently been dredged from the North Lagoon and disposed of off-site, and dredging operations were underway at the South Lagoon at the time of the site assessment. However because of the potential presence of residual CCW, and because the North and South Lagoons have not been formally closed in compliance with applicable federal or state closure/reclamation regulations, CDM Smith has completed the condition assessment of the two impoundments as per USEPA requirements.

<u>FirstEnergy's Comment No. 5</u> – FirstEnergy contends that the observed lateral movement of the concrete crib retaining wall located near the southwest corner of the North Lagoon does not adversely impact the structural integrity of the lagoon.

CDM Smith Action - After further study and investigation, CDM Smith agrees with FirstEnergy and has revised the Final Report accordingly.

<u>FirstEnergy's Comment No. 6</u> – FirstEnergy contends that since CDM Smith's site assessment, all coal has been removed from the coal pile area and the lagoons are not receiving runoff from the coal pile.

CDM Smith Action - CDM Smith cannot confirm that all coal has been removed. Section 4.2.3 has not been revised.

<u>FirstEnergy's Comment No. 7</u> – FirstEnergy states that liquids are discharged directly from the North and South Lagoons to the Cheat River only when flows are in excess of the 25- year, 24-hour storm. In all other instances, liquids from the North and South Lagoons are discharged to an on-sight wastewater treatment plant and then discharged to the Cheat River.

CDM Smith Action - CDM Smith has revised Section 4.2.3 of the Final Report to reflect FirstEnergy's statement.

<u>FirstEnergy's Comment No. 8</u> – FirstEnergy states that outright failure of the North and South Lagoons' embankments would result in but minimal economic and environmental impact.

CCW Impoundment Condition Assessment Report Albright Power Station (Round 12, CLIN 012) Page 3

CDM Smith Action - CDM Smith recommended, in the Draft Report dated November 2012, hazard ratings of LOW to the North and South Lagoons. CDM Smith's recommendation is based on the USEPA classification system as presented on Page 2 of the USEPA checklist and CDM Smith's review of the site and downstream areas. CDM Smith's assessment found it is likely that failure or miss-operation of the lagoons embankment(s) would result in low economic loss and environmental damage to adjacent waterways and downstream areas and that loss of human life as a result of failure is not anticipated. CDM Smith believes a hazard rating of LOW is appropriate and that it is also consistent with FirstEnergy's assessment. Accordingly, the Final Report recommends a hazard rating of LOW for the North and South Lagoons.

Please call or email with any questions.

Sincerely,

William J. Friers, P.E. Senior Civil Engineer

CDM Smith
